INTRODUCTION

The U. S. Geological Survey deployed 120 refraction seismometers in Chalfant Valley, just north of Bishop, California, on August 3, 1986 to record aftershocks of the July 21, $M_L = 6.4$ earthquake. This experiment occurred during the return trip from a multi-institutional seismic experiment in Northern Nevada. The primary goal of this experiment was to measure the seismic coda using two cross-arrays. Centered about 4 km east of the main shock, a N-S connecting line ties the arrays together (Figure 1), and can be used for crustal modeling of the immediate area. The high quality and dense spacing of the data may also be suitable for source imaging, and analysis of radiation patterns and the influence of local geology.

Located at the north end of Owens Valley, Chalfant Valley is within the Basin and Range Province. It is bounded by N-S trending normal faults with the White Mountains on the east, and the Benton Range on the west. The Bishop Volcanic Tablelands rise from the Chalfant Valley, around the southern end of the Benton Range, to Long Valley Caldera 25 km northwest of the main shock. Mesozoic and Paleozoic low grade metamorphic rocks and Mesozoic plutonic rocks make up the basement exposed in the White Mountains and the Benton Range (Crowder and Sheridan, 1972). The eruption of Long Valley Caldera 700,000 years B.P. (Cockerham and Corbett, 1987) deposited the Bishop Tuff that makes up the Volcanic Tablelands. The instrument line traverses various grades of Bishop Tuff and alluvium. Numerous N-S trending normal faults are located west of the deployment line (Figures 1, and 2). Surface fractures from the 1986 earthquake sequence (Lienkaemper et al., 1987) occur along faults in the Volcanic Tablelands, as well as along the White Mountain Frontal Fault Zone (WMFFZ) (Figure 1). Although the Tableland faults and the WMFFZ are mapped as normal faults (Crowder and Sheridan, 1972), strike-slip motion is predominately observed (Cockerham and Corbett, 1987). The dextral slip of the mainshock is consistent with the right lateral slip observed on the 1872 Owens Valley earthquake south of Bishop (Cockerham and Corbett, 1987).

This report displays the digital data available on magnetic tape in SEG-Y format. Nine aftershocks located by the Central California Seismic Network (CALNET) were selected and digitized. Other aftershocks were recorded and could be digitized, but were not located at the time of this report.

DESCRIPTION OF SURVEY

The recording geometry consists of two dense N-S, E-W cross-arrays connected by a less dense N-S trending line. Instrument spacing on the connecting line is about 300 m, whereas the denser cross-arrays have about 60 m spacing. The connecting line is about 23 km long consisting of 65 instrument sites. The northern cross-array has dimensions of approximately 1.0 km N-S by 1.0 km E-W with 13 instrument sites in both directions. Similarly, the southern cross-array is approximately 1.3 km N-S by 1.0 km E-W, with 14 and 11 instrument sites, respectively (Figure 2). The N-S connecting line contains instrument locations 101 to 165. Location numbers in the 200's refer to the denser cross-arrays, with 201 to 225 for the north array, and 251 to 276 for

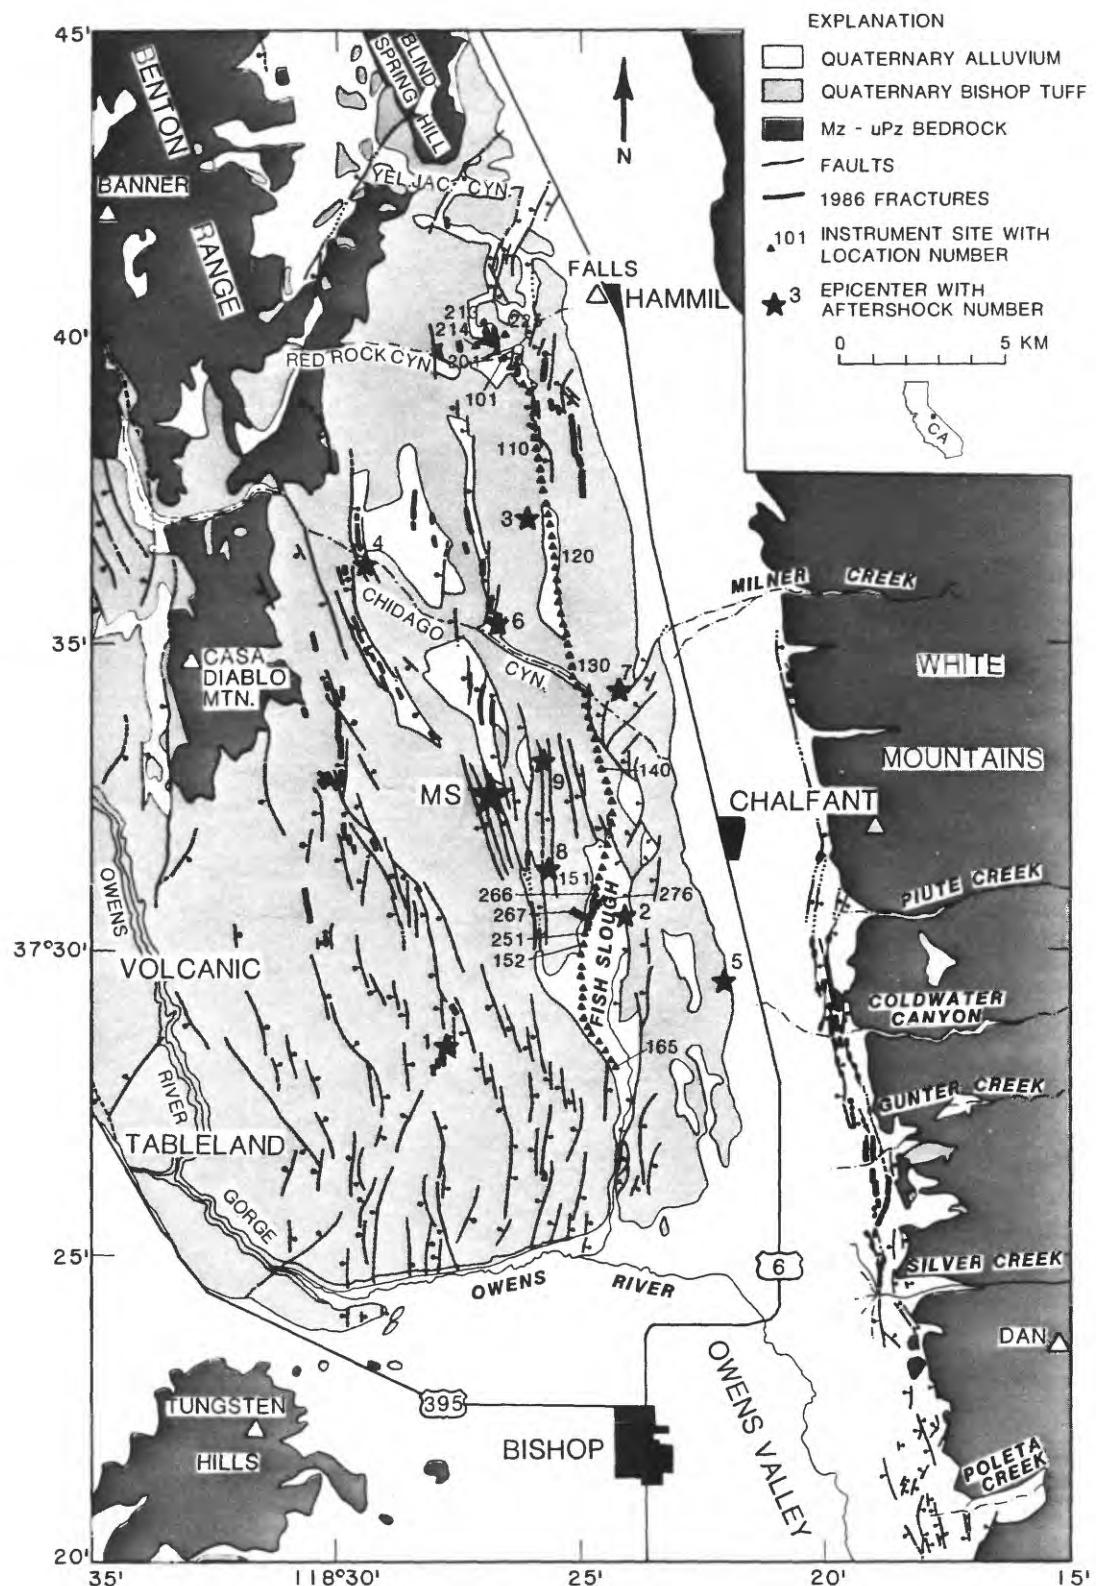

Figure 1. General geologic location map of seismograph array. The large star marked MS locates the main shock of 21 July 1986 (after Lienkaemper et al., 1987, Figure 2).

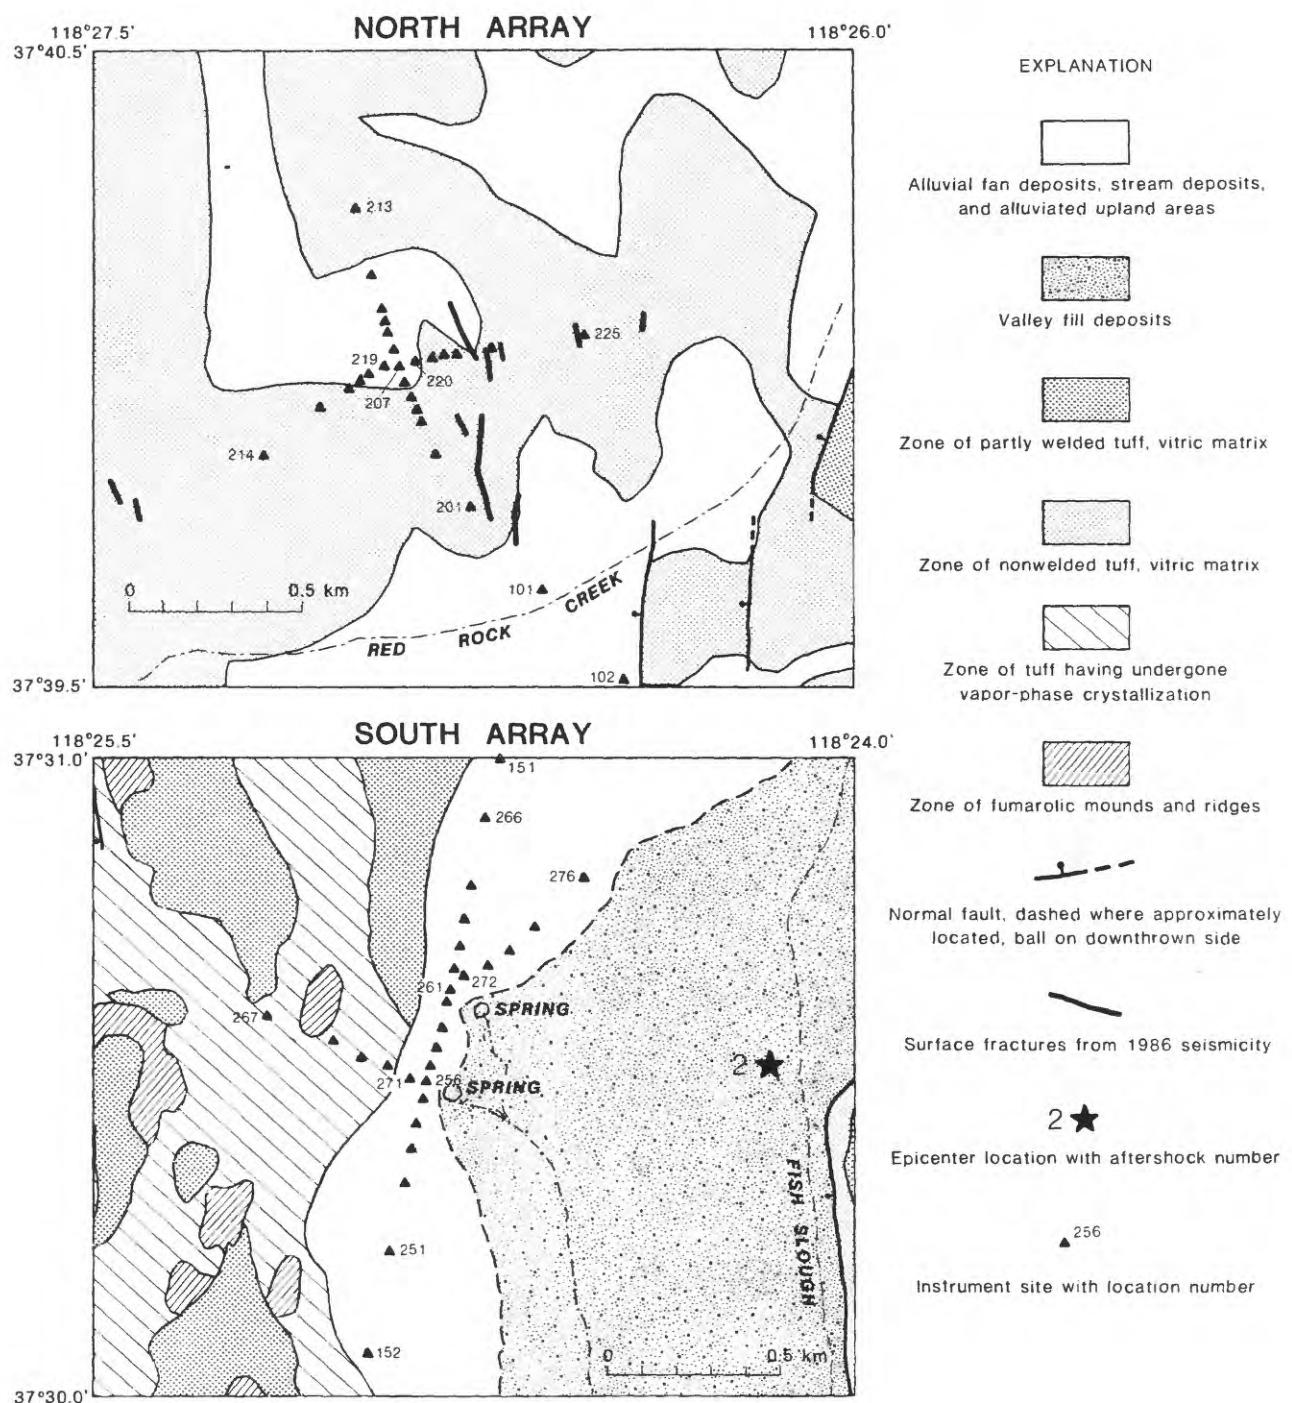

Figure 2. Detailed geologic location maps of the dense cross-arrays (Crowder and Sheridan, 1972, Lienkaemper et al., 1987).

the south array (Figures 1 - 2, and Table 1). Instrument locations and elevations on the connecting N-S line are accurate to ± 25 m and were determined from 1:62,500 topographic maps and 1:24,000 orthophoto quadrangles. The dense arrays were surveyed with an electronic distance meter (EDM) and have a horizontal accuracy of about ± 5 m. Once deployed, the instruments activate and record automatically for the desired time intervals.

The instruments were programmed to record on August 3, 1986 during four 27 minute time windows: 4:00:00 - 4:27:00, 6:00:00 - 6:27:00, 15:00:00 - 15:27:00, and 17:00:00 - 17:27:00 (UTC). Immediately before each recording window, each instrument also recorded a calibration. The northern and southern arrays recorded all nine events. Unfortunately, the N-S connecting line only recorded during the 4:00:00 and 6:00:00 windows. Therefore, only three of the nine digitized events were recorded by the N-S line (Table 2).

INSTRUMENTATION AND DATA REDUCTION

Seismic Recorders

The instruments used in this survey are usually deployed in seismic refraction experiments. The portable seismographs are individual units, each equipped with a memory board to store recording times, and a recording system. Six teams deploy the 120 suitcase-sized instruments that weigh about 18 kg each (Healy and others, 1982). Two 6-volt rechargeable batteries power each recorder, and a crystal controlled clock serves as the instrument chronometer with an accuracy of about $1:10^{-7}$. Before each deployment, technicians program up to 10 recording times and synchronize the chronometer of each recorder with a master clock. The master clock has a drift rate of about 1 msec per week and is synchronized to a GOES satellite clock or a rubidium standard reference clock, accurate to approximately 3 msec/yr, which is periodically calibrated to an averaged WWVB reference signal. The National Bureau of Standards' cesium-beam clocks control the WWVB and GOES signals. After retrieval, the instruments' chronometer drift is noted relative to the master clock. During deployment a vertical-component 2 Hz geophone is oriented and buried. Ten minutes before the recording time, the instruments stabilize and then record a calibration, which includes a seismometer pulse, amplifier step, and 1, 10, 100, and 1000 mV, 10 Hz sine wave calibration signals. The recording window proceeds immediately after the calibration. The seismometer output is divided, without attenuation, and amplified at selected gains by three parallel amplifiers, which allows for recording over a dynamic range of 84 db (Figure 3). Output from the three amplifiers and a serial IRIG-E time code pulse train are frequency modulated, summed with a tape speed compensation reference signal, and analog recorded on 60 minute cassette tape. The system measures velocity with a frequency response that peaks at 6 Hz and sharply rolls off beyond 20 Hz, avoiding 60 Hz contamination (Figure 4).

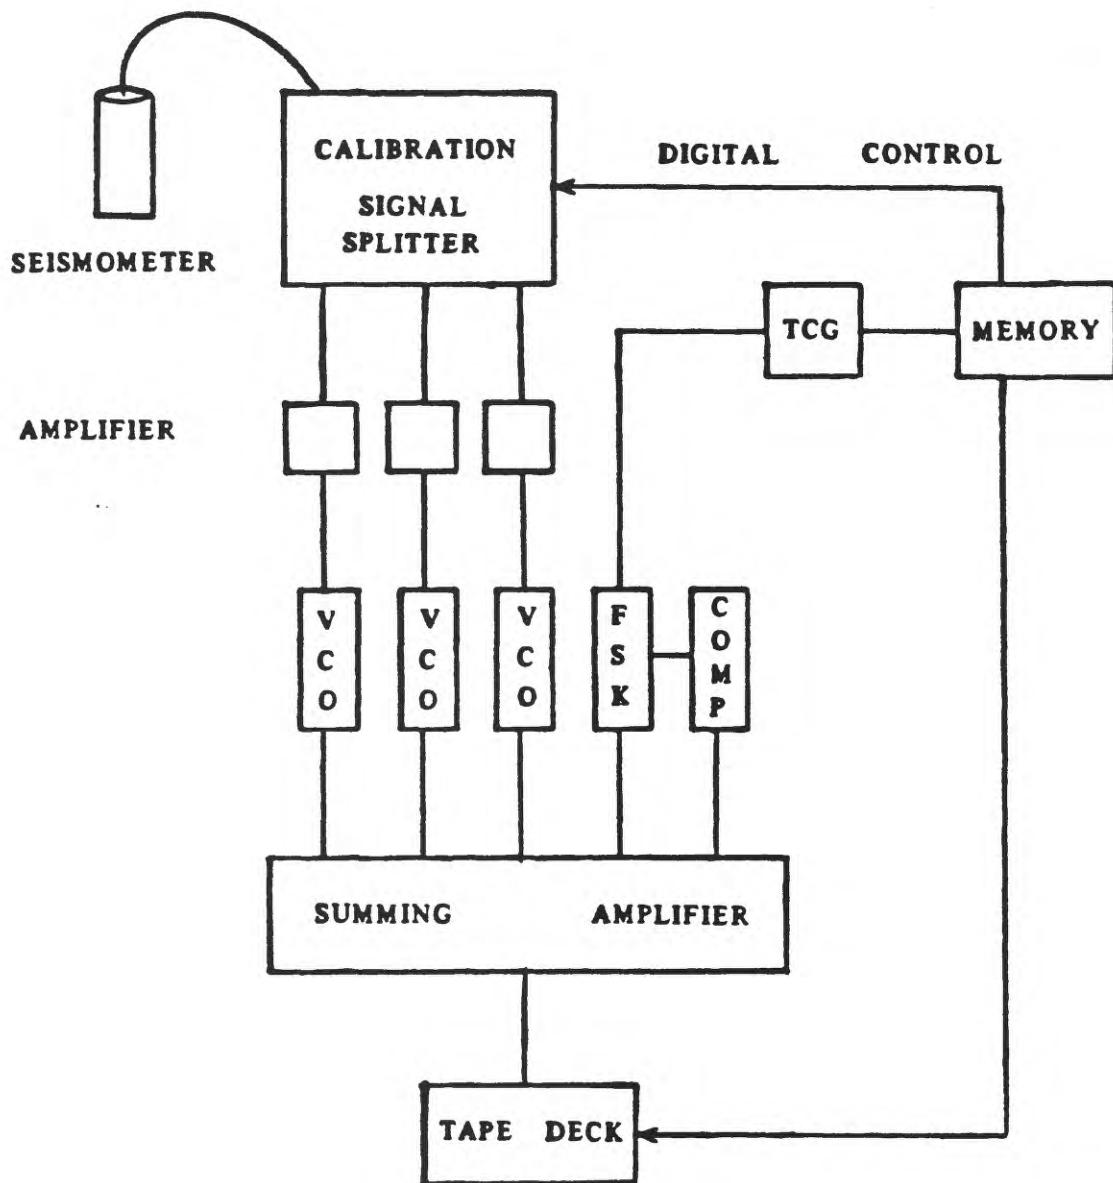

Data Reduction

Aftershocks were chosen, digitized, and plotted as record sections. The quality of each trace is assessed and the trace is redigitized if necessary. Events were chosen from stripchart playbacks of recordings from three instruments, one located towards either end of the main line, and one in the middle. Dozens of aftershocks were recorded during the experiment, averaging about three every minute (Figure 5). Any event located by CALNET with little or no interference from other events was digitized. The M_L of the events digitized range from 0.9 to 1.7; the depths range from 4.7 km to 15.3 km. Location uncertainties are within 1 km for 7 of the 9 events; two events (4 and 8) were poorly located (Table 2). However, the hypocenter locations could be improved by the addition of the traveltimes from this data set, since the aftershock region spans most of the deployment line. Initially, aftershocks 1 and 3 were digitized for 40 seconds with a sampling rate of 100 samples/sec, beginning 4 seconds before the origin time. Since most of the coda durations were less than 20 seconds, all events were digitized for 20 seconds with a sampling rate of 200 samples/sec. Therefore, both record lengths are available for aftershocks 1 and 3. Record sections (Figures 6-26) are displayed to maximum recording length available, and each trace is normalized to its maximum amplitude. Due to the relative position of the recording array to some of the aftershocks, many record sections are displayed as fans, i.e. distance plotted relative to a trace at the end of the record section (such as in Figure 6). The remaining record sections are plotted by epicentral distance. Noisy traces with little or no seismic signal are saved in the data file with a negative unit number (not location number, see definitions in Appendix A) and excluded from the record section. Each trace is assigned a tape grade code describing the quality of the recording and performance of the recorder. Tape grade codes are included in the Field Data Tables (Appendix A).

ARCHIVE TAPE

A SEG-Y (Barry and others, 1975, Appendix B) tape for this data set may be obtained from:

National Geophysical Data Center
NOAA/NGDC E/GC1
325 Broadway
Boulder, CO 80303
Telephone: (303) 497 - 6472

COMP = COMPENSATION
FSK = FREQUENCY SHIFT KEYING
TCG = TIME CODE GENERATOR
VCO = VOLTAGE-CONTROLLED OSCILLATOR

Figure 3. Schematic diagram of a recording unit (from Healy et al., Figure 13).

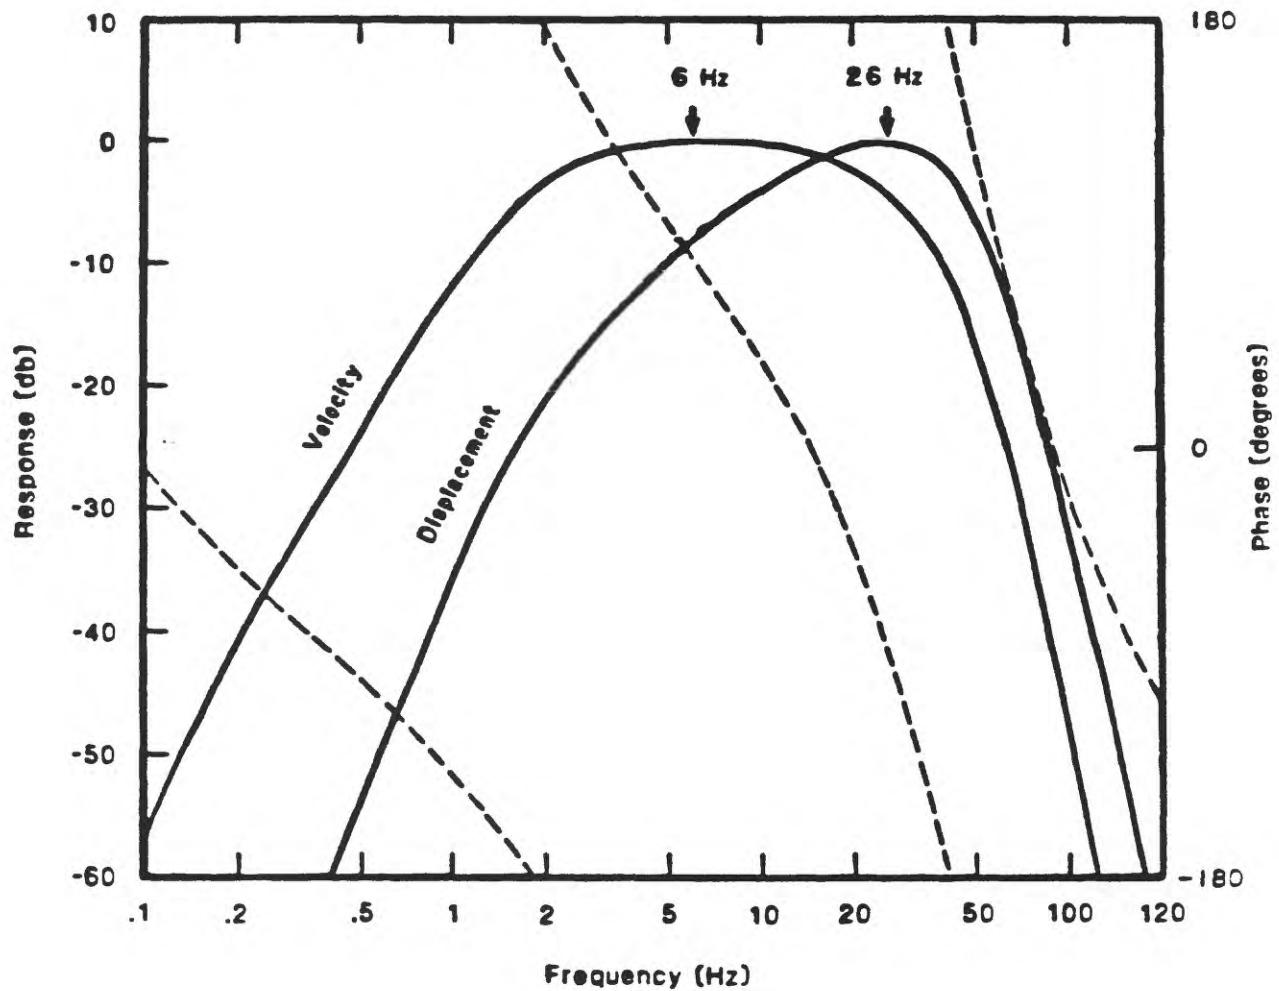

Figure 4. Theoretical transfer-function curves for the USGS short-period seismic refraction system. Solid line: displacement and velocity normalized amplitude, dashed line: phase (displacement). Maximum velocity response is at 6 Hz, maximum displacement response is at 26 Hz (from Dawson and Stauber, 1986, Figure 3).

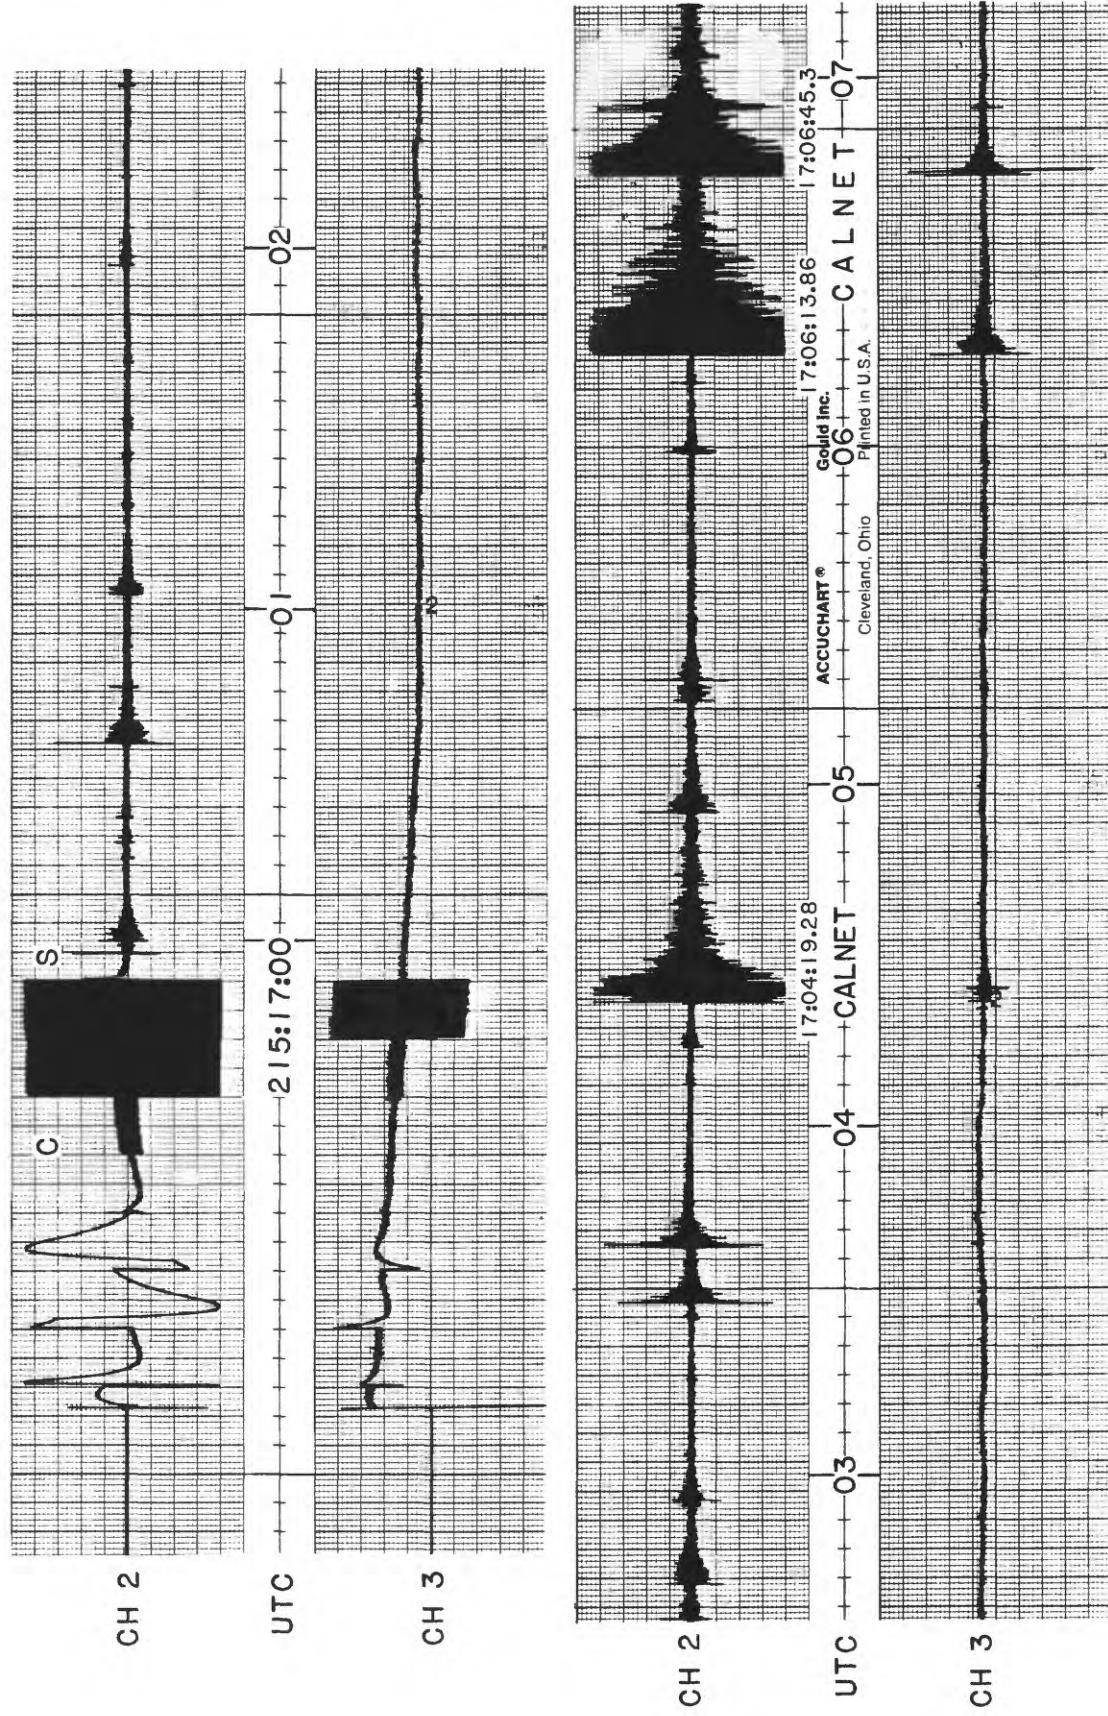

Figure 5. Strip chart play back from location 264 on Julian day 215 with a start time of 17:00:00 (UTC). The letters R, C, and S denote the seismometer release, calibration sequence, and beginning of the seismic trace, respectively. The upper trace is channel 2 with 12 db attenuation, and the lower trace is channel 3 with 48 db attenuation. Numbered tics are approximate minutes. Events located by CALNET are indicated. Origin times are labeled beneath the digitized events. Figure continued on next two pages.

ACKNOWLEDGEMENTS

Pat Berge, Robert Colburn, Janice Murphy, Julie Shemeta, and Dean Whitman programmed and deployed the recording instruments. Instrument locations were laser surveyed with an EDM by Leif Wennerburg and Dean Whitman. Bruce Julian and Paul Spudich designed the recording array. Special thanks to James Lienkaemper for the use of his drafts for Figure 1. Also appreciated are the suggestions from Walter Mooney during the compilation of this report.

APPENDIX A

Field Data Tables

The field data tables contain information related to the seismic recorders and digitizing results. Aftershock numbers occur in chronological order and correspond to aftershock numbers on the record sections. Column headings are defined below:

Loc	- location number of the sesmic recorder location (see Table 1)
Dist (km)	- epicentral distance to the recorder
Azim (deg)	- azimuth from the epicenter to the recorder (clockwise from north)
Db	- amplifier attenuation setting (db) of the digitized channel. The gain is determined by subtracting the given attenuation from a total gain of 96 db.

Tape Grade Scale

The tape grade scale is referenced by the last column in the field data tabel. Seismograph performance and trace quality are defined by the scale below.

0	OK
1	No run, blank tape
2	No seismic, or low seismic
3	Bad time code
4	Missed turn on time
5	Not deployed
6	Clipped trace
7	High noise
8	Timing error 1 - off by days, hours, or minutes (trace may be recoverable)
9	Partial record
10	Data missing
11	Tape ends before signal
12	Timing error 2 - trace off by seconds.
13	No tape for this recording window

APPENDIX B

Archive Tape Data Format

Archive data tapes are written in SEGY standard format (Barry et al., 1975). Recording density is 1600 bpi, phase encoded (PE). In order to accommodate seismic refraction data, some minor changes have been made to the tape header fields. A complete list of header fields is provided in the card image portion of the reel identification header, shown below:

```

C 1 REEL IDENTIFICATION HEADER BYTES:
C 2 3217 -3218 sampling interval (microsecs).
C 3 3221 -3222 number of samples per trace.
C 4 3225 -3226 data sample format code.
C 5 3255 -3256 measurement system (1 = meters; 2 = feet).
C 6
C 7
C 8 TRACE IDENTIFICATION HEADER BYTES:
C 9   1 -   4 trace sequence number within reel.
C10   5 -   8 trace sequence number within reel.
C11   9 -  12 station location number.
C12  29 -  30 trace ID code (1 = seismic data).
C13  37 -  40 shotpoint-receiver distance (M).
C14  41 -  44 station elevation (M).
C15  45 -  48 shotpoint elevation (M).
C16  49 -  52 source depth (M).
C17  69 -  70 scalar to be applied to all elevations.
C18  71 -  72 scalar to be applied to all coordinates.
C19  73 -  76 shotpoint coordinate - X.
C20  77 -  80 shotpoint coordinate - Y.
C21  81 -  84 receiver coordinate - X.
C22  85 -  88 receiver coordinate - Y.
C23  89 -  90 coordinate units (1 = meters; 2 = seconds of arc).
C24 115 - 116 number of samples in this trace.
C25 117 - 118 sample interval in microseconds for this trace.
C26 121 - 122 instrument attenuation in db.
C27 157 - 158 shot time - year.
C28 159 - 160 shot time - day of year.
C29 161 - 162 shot time - hour of day (24 hour clock).
C30 163 - 164 shot time - minute of hour.
C31 165 - 166 shot time - second of minute.
C32 167 - 168 time basis code (2 = GMT).
C33 181 - 182 shot time - milliseconds.
C34 183 - 184 shotpoint location number.
C35 185 - 186 recording instrument unit number.

```

C36 191 - 192 distance weighting exponent (hundredths).
C37 193 - 194 shot sequence number (shot number).
C38 195 - 196 shot size (kg).
C39 197 - 200 shot point - station azimuth (second of arc).
C40 201 - 204 time of first point minus time (msec).

The data point format is "32 bit floating point", and the appropriate bytes (3225-3226) of the binary reel id header contain a value of 1. The trace amplitudes have not been adjusted for instrument gain, but the gain correction factor can be estimated from the instrument attenuation value (att) specified in bytes 121-122. To correct for gain, the data should be demeaned and then multiplied by:

$$\frac{(\text{att}/20)}{10}$$

The measurement system (bytes 3255-3256 of the binary reel header) is set to 1, meters.

Shot point and receiver coordinates are in seconds of arc (byte field 89-90). The coordinate scalar multiplier (bytes 71-72) is set to -100, so the coordinates (bytes 73-88) are in hundredths of a second of arc.

Bytes 157-166 and bytes 181-182 refer to the shot detonation time. The time of the first data sample is found by adding the shot detonation time to the time specified in bytes 201-204.

Since there is no weighting of amplitudes with distance for archive tapes, the distance weighting exponent (bytes 191-192) is not used.

Shot sequence number (bytes 193-194) refers to the order in which shots were fired during the field campaign.
